# Introduction

# Problem statement

- $n$  users,  $m$  movies
- $R^{\text{train}} = (r_{ij})_{ij} \in \mathcal{M}_{n,m}(\mathbb{R}), \forall i, j, r_{ij} \in [0, 5] \cup \{\emptyset\}$
- $R^{\text{test}} = (\hat{r}_{ij})_{ij} \in \mathcal{M}_{n,m}(\mathbb{R}), \forall i, j, \hat{r}_{ij} \in [0, 5] \cup \{\emptyset\}$
- Goal : Infer ratings of a user for a movie in  $R^{\text{test}}$  with  $\{\text{ratings of other users for this movie}\}$  and  $\{\text{ratings of this user for other movies}\}$  in  $R^{\text{train}}$ .

## Results of lecun-team

Method	RMSE test set	RMSE platform	Time	Rank platform
GD MF	0.88	0.86	20s	1
ALS MF	0.91	0.87	15s	1
iDMF	<b>0.85</b>	<b>0.80</b>	250s*	1

GD MF : Gradient descent matrix factorization

ALS MF : Alternating least squares matrix factorization

iDMF : improved deep matrix factorization

\* : improvable by parallelization

## Method

# Deep matrix factorization[1]

- Dataset :  $(\text{user}_i, \text{movie}_j), \forall i, j \text{ s.t. } r_{ij} \neq \emptyset$
- 2 neural networks :  $\text{NN}_{\theta_1}^{\text{movie}} : \mathbb{R}^n \rightarrow \mathbb{R}^{256}, \text{NN}_{\theta_2}^{\text{user}} : \mathbb{R}^m \rightarrow \mathbb{R}^{256}$
- Compute cosine similarity
$$\delta_{\theta_1, \theta_2}(\text{user}_i, \text{movie}_j) = \frac{\langle \text{NN}_{\theta_1}^{\text{movie}}(\text{movie}_j), \text{NN}_{\theta_2}^{\text{user}}(\text{user}_i) \rangle}{\|\text{NN}_{\theta_1}^{\text{movie}}(\text{movie}_j)\| \|\text{NN}_{\theta_2}^{\text{user}}(\text{user}_i)\|} \in [-1, 1]$$
- Rescale  $\delta_{\theta_1, \theta_2}(\text{user}_i, \text{movie}_j) : [-1, 1] \rightarrow [0, 1]$ , and  $r_{ij} : [0, 5] \rightarrow [0, 1]$
- Compute binary cross entropy :  $\text{BCE}(\delta_{\theta_1, \theta_2}(\text{user}_i, \text{movie}_j), r_{ij})$  and run SGD with respect to  $\theta_1$  and  $\theta_2$

# Interpretation

Figure – T-SNE of projections, view 1

Figure – T-SNE of projections, view 2

Figure – Project movies and users in the same space such that the more a user is likely to like a movie, the more the projections of the movie is close to the projection of the user in this space.

## Improvements

# Improvements

- Learning the scalar product (solving over-regularization)
- Adding metadata
- Adding denoising auto-encoder (adding compatible regularization)
- Adding ensembling of K folds

## Zoom on learning the scalar product

- Learn  $S \in \mathcal{M}_{256,256}(\mathbb{R})$
- Use  $\langle \cdot, \cdot \rangle : (X, Y) \rightarrow X^T S^T S Y$  to compute cosine similarity
- This gives the model the freedom to project movies and users into two separate subspaces, which is perhaps more suited to the problem, and then learn a distance measure to compare elements in these two separate subspaces.
