Supervised Learning

Given a labeled dataset (\mathbf{X}, \mathbf{Y}) , we would like to learn a mapping from data space to label space.

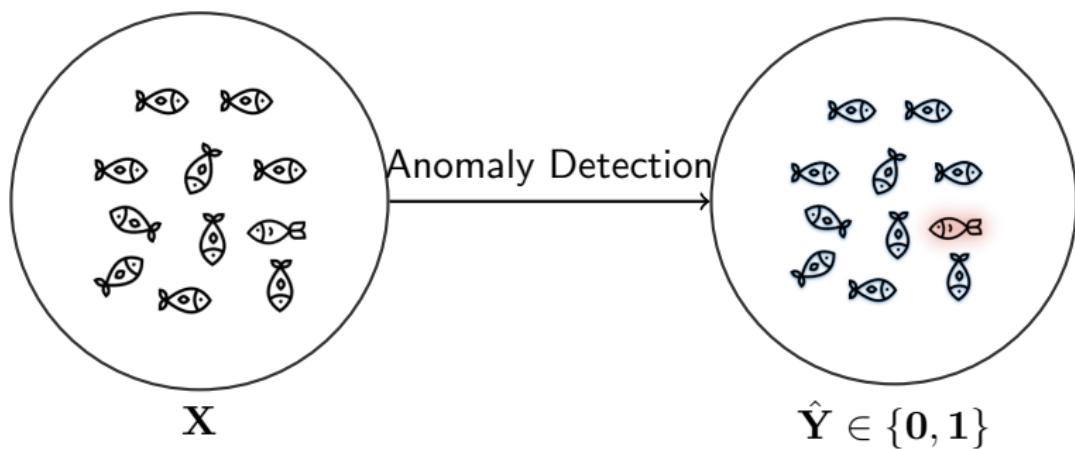

Unsupervised Learning: Clustering

Given an unlabeled dataset (\mathbf{X}), we would like to learn: **How to group objects into categories?**

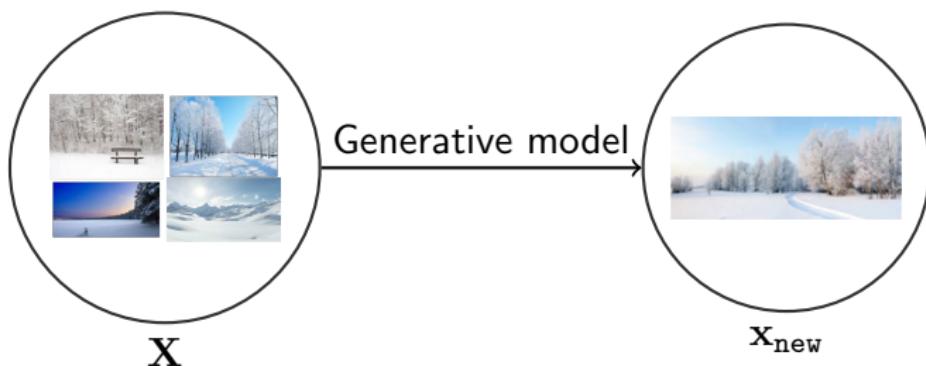

Anomaly detection

Given an unlabeled dataset (\mathbf{X}), we would like to learn: How to identify observations differing significantly from the majority of data?

Unsupervised learning: Generative Models

Given an unlabeled dataset (\mathbf{X}), we would like to learn: How to generate a new observation from the same distribution (unknown) of dataset?

Goal

Generative models "learn" a joint distribution over a dataset. They are mostly used for sampling applications or density estimation.

- ① (Sampling) A generative model learns to fit a model over observations so one can sample novel data from the model,
 $\mathbf{x}_{new} \sim p_{\theta}(\mathbf{x})$
- ② (Density estimation) A model learns to estimate the probability of observations. Given a datapoint \mathbf{x} the model, what is the probability of \mathbf{x} belong to the dataset?

Unsupervised learning: Generative Models

Given an unlabeled dataset (\mathbf{X}), we would like to learn: How to generate a new observations from the same distribution (unknown) of dataset?

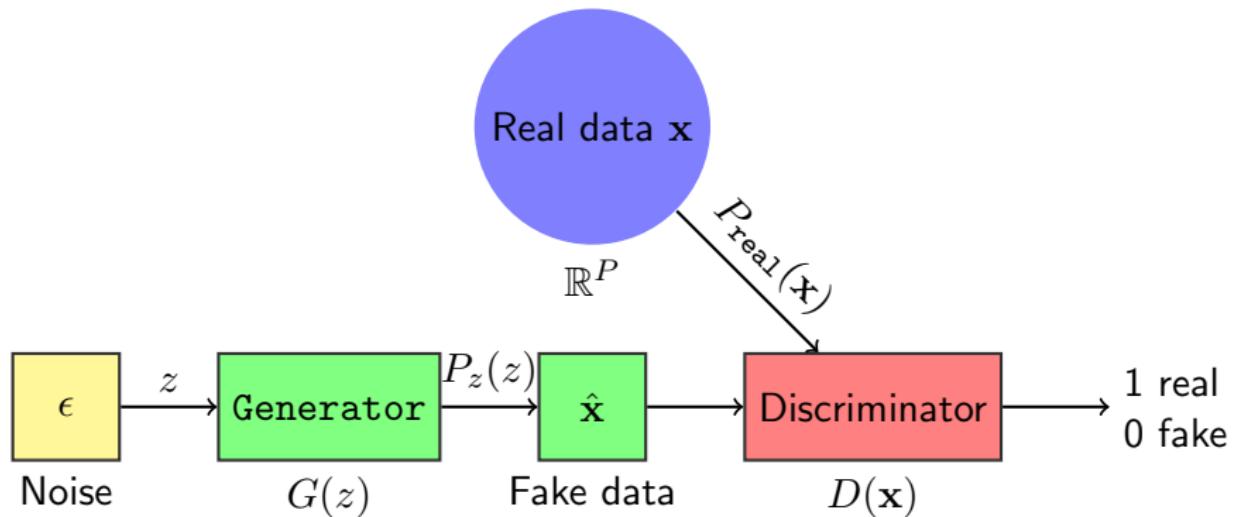

Generative Adversarial Networks (GANs)

[Goodfellow et al., 2014]

Generative Adversarial Networks (GANs)

[Goodfellow et al., 2014]

“The coolest idea in machine learning in the last 20 years” - Yann LeCun.

Generative Adversarial Networks (GANs)

We require that the discriminator D recognises examples from the $P_{\text{real}}(\mathbf{x})$ distribution,

$$\mathbb{E}_{\mathbf{x} \sim P_{\text{real}}(\mathbf{x})} [\log D(\mathbf{x})] \quad \text{Decision over Real Data}$$

where \mathbb{E} denotes the expectation. This term comes from the “1” class of the log-loss function.

Additionally, we would like to trick the discriminator via a good generator G . Thus, the term comes from “0” class of the log-loss function:

$$\mathbb{E}_{z \sim P_z(z)} [\log(1 - D(G(z)))] \quad \text{Decision over Fake Data}$$

Generative Adversarial Networks (GANs)

Questions: Optimal Discriminator? Optimal Generator? We define:

$$V(G, D) := \mathbb{E}_{\mathbf{x} \sim P_{\text{real}}(\mathbf{x})} [\log D(\mathbf{x})] + \mathbb{E}_{z \sim P_z(z)} [\log(1 - D(G(z)))]$$

What should be an optimal discriminator?

Generative Adversarial Networks (GANs)

Questions: Optimal Discriminator? Optimal Generator? We define:

$$V(G, D) := \mathbb{E}_{\mathbf{x} \sim P_{\text{real}}(\mathbf{x})} [\log D(\mathbf{x})] + \mathbb{E}_{z \sim P_z(z)} [\log(1 - D(G(z)))]$$

What should be an optimal discriminator?

$$D^* = \arg \max_D V(G, D)$$

Now, given this optimal discriminator D^* , what should be an optimal generator?

Generative Adversarial Networks (GANs)

Questions: Optimal Discriminator? Optimal Generator? We define:

$$V(G, D) := \mathbb{E}_{\mathbf{x} \sim P_{\text{real}}(\mathbf{x})} [\log D(\mathbf{x})] + \mathbb{E}_{z \sim P_z(z)} [\log(1 - D(G(z)))]$$

What should be an optimal discriminator?

$$D^* = \arg \max_D V(G, D)$$

Now, given this optimal discriminator D^* , what should be an optimal generator?

$$G^* = \arg \min_G V(G, D^*)$$

This is called the *minimax formulation*, since the generator and discriminator are playing a *zero-sum game* against each other:

$$\min_G \max_D V(G, D) \tag{1}$$

Generative Adversarial Networks (GANs)

$$\begin{aligned} & \min_G \max_D V(G, D) := \\ = & \mathbb{E}_{\mathbf{x} \sim P_{\text{real}}(\mathbf{x})} [\log D(\mathbf{x})] + \mathbb{E}_{z \sim P_z(z)} [\log(1 - D(G(z)))] \\ & \text{by Radon-Nikodym Theorem} \\ = & \mathbb{E}_{\mathbf{x} \sim P_{\text{real}}(\mathbf{x})} [\log D(\mathbf{x})] + \mathbb{E}_{x \sim P_{g(\mathbf{x})}} [\log(1 - D(x))] \\ = & \int_x (P_{\text{real}}(\mathbf{x})[\log D(\mathbf{x})] + P_{g(\mathbf{x})}[\log(1 - D(x))]) dx \end{aligned}$$

Optimal Discriminator: G fixed.

$$V(G, D) = \int_x \left(P_{\text{real}}(\mathbf{x})[\log D(\mathbf{x})] + P_{g(\mathbf{x})}[\log(1 - D(x))] \right) dx \quad (2)$$

- Note that $f(x) = a \log(x) + b \log(1 - x)$, has minimum in $x^* = \frac{a}{a+b}$
- $P_{\text{real}}(\mathbf{x}) \log D(\mathbf{x}) + P_{g(\mathbf{x})} \log(1 - D(x))$ the optimal discriminator $D^*(\mathbf{x}) = \frac{P_{\text{real}}(\mathbf{x})}{P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x})}$

Given an optimal discriminator $D^*(\mathbf{x})$, find
 $\min_G V(G, D^*)$.

$$\begin{aligned}V(G, D^*) &= \int_x (P_{\text{real}}(\mathbf{x}) \log \left(\frac{P_{\text{real}}(\mathbf{x})}{P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x})} \right) \\&\quad + P_{g(\mathbf{x})} \log \left(1 - \frac{P_{\text{real}}(\mathbf{x})}{P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x})} \right)) dx \\&= \int_x (P_{\text{real}}(\mathbf{x}) \log \left(\frac{P_{\text{real}}(\mathbf{x})}{P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x})} \right) \\&\quad + \int_x P_{g(\mathbf{x})} \log \left(\frac{P_g(\mathbf{x})}{P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x})} \right)) dx \\&= -\log(4) + \int_x (P_{\text{real}}(\mathbf{x}) \log \left(\frac{P_{\text{real}}(\mathbf{x})}{(P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x}))/2} \right) \\&\quad + \int_x P_{g(\mathbf{x})} \log \left(\frac{P_g(\mathbf{x})}{(P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x}))/2} \right)) dx\end{aligned}$$

Given an optimal discriminator $D^*(\mathbf{x})$, find
 $\min_G V(G, D^*)$.

$$\begin{aligned} V(G, D^*) &= -\log(4) + \int_x (P_{\text{real}}(\mathbf{x}) \log \left(\frac{P_{\text{real}}(\mathbf{x})}{(P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x}))/2} \right) dx \\ &\quad + \int_x P_{g(\mathbf{x})} \log \left(\frac{P_g(\mathbf{x})}{(P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x}))/2} \right) dx \end{aligned}$$

¹Divergence Jensen–Shannon is a symmetrized and smoothed version of the Kullback–Leibler divergence, $Div_{JS}(p||q) = \frac{1}{2}\text{KL}(p||m) + \frac{1}{2}\text{KL}(q||m)$ where $m = p + q$

Given an optimal discriminator $D^*(\mathbf{x})$, find
 $\min_G V(G, D^*)$.

$$\begin{aligned} V(G, D^*) &= -\log(4) + \int_x (P_{\text{real}}(\mathbf{x}) \log \left(\frac{P_{\text{real}}(\mathbf{x})}{(P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x}))/2} \right) dx \\ &\quad + \int_x P_{g(\mathbf{x})} \log \left(\frac{P_g(\mathbf{x})}{(P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x}))/2} \right) dx \end{aligned}$$

by means of Divergence Jensen–Shannon¹ we can obtain:

$$V(G, D^*) = -\log(4) + 2\text{Div}_{\text{JS}}(P_{\text{real}} || P_g) \quad (3)$$

¹Divergence Jensen–Shannon is a symmetrized and smoothed version of the Kullback–Leibler divergence, $\text{Div}_{\text{JS}}(p || q) = \frac{1}{2}\text{KL}(p || m) + \frac{1}{2}\text{KL}(q || m)$ where $m = p + q$

Summarising, we have:

- Optimal Discriminator: $D^*(\mathbf{x}) = \frac{P_{\text{real}}(\mathbf{x})}{P_{\text{real}}(\mathbf{x}) + P_g(\mathbf{x})}$
- $\min_G V(G, D^*) = 2\text{Div}_{\text{JS}}(P_{\text{real}} || P_g) - \log 4$

Thus,

- $\min_G V(G, D^*)$ is obtained when $P_{\text{real}} = P_g$,
- $D^*(\mathbf{x}) = \frac{1}{2}$
- and $\min_G \max_D V(G, D) = -\log 4$

How to Train a GAN?

Bad news: GANs are hard to train. **Tips and tricks to make GANs work** <https://github.com/soumith/ganhacks>

- Use others loss functions.
- Avoid Sparse Gradients: ReLU, MaxPool
- Use Deep Convolutional Generative Adversarial Networks when you can. It works!
- Use SGD for discriminator and ADAM for generator
- Use Dropouts in G in both train and test phase
- ...

“In theory, there is no difference between theory and practice. In practice, there is.”

[Isola et al., 2017]

Conclusion on GANs

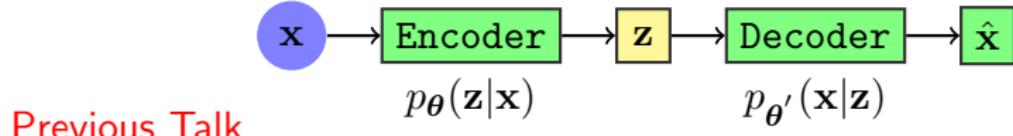

- Interesting for generation from data.
- Conditioning can help to include priori information.
- Generated images (as well as other types of data) are already very realistic

Generative Adversarial Networks (GANs)

- Two steps training: Discriminator and Generator.
- In "testing" only the Generator is used.
- Pretty fast in "testing"
- Hard to optimise.

Variational Autoencoders

Previous Talk

- One step training: Autoencoder and Decoder.
- In "testing" only the Decoder is used and the generation is done by "walking" in the feature space.
- Pretty fast in "testing"
- Easy to use in simple case. Not necessary a good idea in hard problems.

Flow-based models

- Flow models restrict the function to be a chain of invertible functions, called a *flow*, therefore the whole function is *invertible*.
- Given $p_z(\mathbf{z})$ where $\mathbf{x} = f(\mathbf{z})$ and $\mathbf{z} = f^{-1}(\mathbf{x})$ we are looking for $p_x(\mathbf{x})$

$$p_x(\mathbf{x}) = p_z(f^{-1}(\mathbf{x})) \left| \det \left(\frac{\partial f^{-1}(\mathbf{x})}{\partial \mathbf{x}} \right) \right| \quad (4)$$

Diffusion models

Previous Talk

- The *forward diffusion* process is defined as add a small amount of Gaussian noise to the sample T steps producing a sequence of noisy samples $\mathbf{x}_1, \dots, \mathbf{x}_T$

Questions

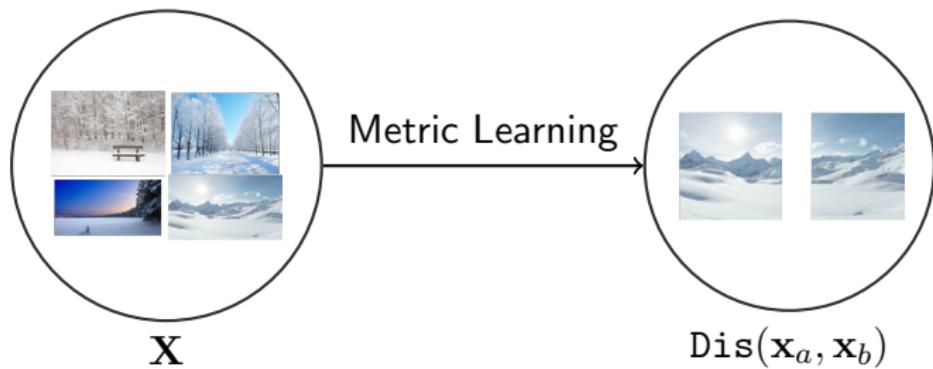

- The word “adversarial” in the acronym for GANs suggest two-players. What are the two players, and what are their respective goals?
- What is the difference between adversarial attacks and adversarial networks?
- If the discriminator is able to detect correctly fake images means that GANs converges: True/False
- Suppose you have a code to generate "city maps" and also a base of real city maps. How can you try to improve the quality of your generator by considering the real images?

Unsupervised learning: Metric Learning

Given an unlabeled dataset (\mathbf{X}), we would like to learn: How to estimate the distance between two objects of \mathbf{X} ?

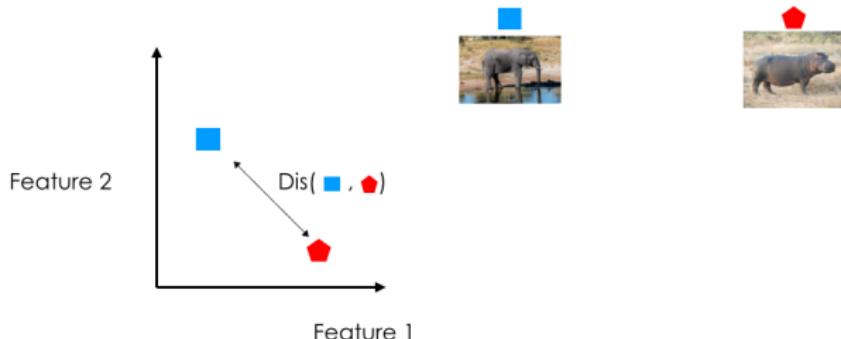

- ① $\text{Dis}(\mathbf{x}, \mathbf{x}') = 0 \iff \mathbf{x} = \mathbf{x}'$ (Identity)
- ② $\text{Dis}(\mathbf{x}, \mathbf{x}) = 0, \forall \mathbf{x}$ (Non-negative)
- ③ $\text{Dis}(\mathbf{x}, \mathbf{x}') = \text{Dis}(\mathbf{x}', \mathbf{x}), \forall \mathbf{x}, \mathbf{x}'$ (Symmetry)
- ④ $\text{Dis}(\mathbf{x}, \mathbf{x}'') > \text{Dis}(\mathbf{x}, \mathbf{x}') + \text{Dis}(\mathbf{x}', \mathbf{x}'')$ (Triangle Inequality)

DL for Metric Learning

Metric Learning has been used in many cases, for example:

- ① Retrieval of Objects: Given a database, find the k-closest point a given example.
- ② Clustering.
- ③ Anomaly detection.
- ④ Pretraining Networks.

Introduction to Metric Learning

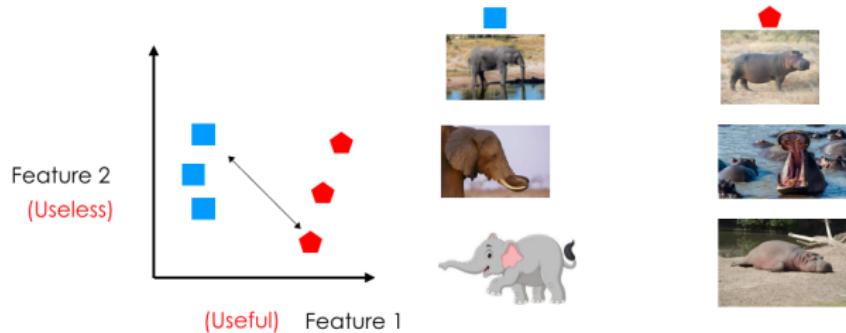

The natural idea is to compute the Euclidean distance:

$$\text{Dis}(\mathbf{x}, \mathbf{y}) = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + \dots} = \sqrt{(\mathbf{x} - \mathbf{y})^T (\mathbf{x} - \mathbf{y})}$$

Introduction to Metric Learning

How to compare observations?

$$\begin{aligned}\text{Dis}(\mathbf{x}, \mathbf{y}) &= \sqrt{w_1(x_1 - y_1)^2 + w_2(x_2 - y_2)^2 + \dots} \\ &= \sqrt{(\mathbf{L}(\mathbf{x} - \mathbf{y}))^T (\mathbf{L}(\mathbf{x} - \mathbf{y}))} \\ &= \sqrt{(\mathbf{x} - \mathbf{y})^T \mathbf{L}^T \mathbf{L} (\mathbf{x} - \mathbf{y})} \\ &:= \sqrt{(\mathbf{x} - \mathbf{y})^T \mathbf{M} (\mathbf{x} - \mathbf{y})}\end{aligned}$$

Introduction to Metric Learning

$$\begin{aligned}\text{Dis}(\mathbf{x}, \mathbf{y}) &= \sqrt{w_1(x_1 - y_1)^2 + w_2(x_2 - y_2)^2 + \dots} \\ &= \sqrt{(\mathbf{L}(\mathbf{x} - \mathbf{y}))^T (\mathbf{L}(\mathbf{x} - \mathbf{y}))} \\ &= \sqrt{(\mathbf{x} - \mathbf{y})^T \mathbf{L}^T \mathbf{L}(\mathbf{x} - \mathbf{y})} \\ &:= \sqrt{(\mathbf{x} - \mathbf{y})^T \mathbf{M}(\mathbf{x} - \mathbf{y})}\end{aligned}$$

The goal in metric learning is to learn \mathbf{M} . Using the fact that a PSD² matrix \mathbf{M} can always be decomposed as $\mathbf{M} = \mathbf{L}^T \mathbf{L}$ for some \mathbf{L} , one can show that both parameterizations are equivalent. In practice, an algorithm may thus solve the metric learning problem with respect to either \mathbf{M} or \mathbf{L}

² \mathbf{B} is Positive Semidefinite $\iff \mathbf{x}^T \mathbf{B} \mathbf{x} \geq 0 \forall \mathbf{x}$

Siamese Neural Network

Given a pair of similar examples $(\mathbf{x}_i, \mathbf{x}_j)$, a Siamese neural network (sometimes called a *twin neural network*) is an artificial neural network that uses the same weights while working in tandem on two different input vectors to compute comparable output vectors.

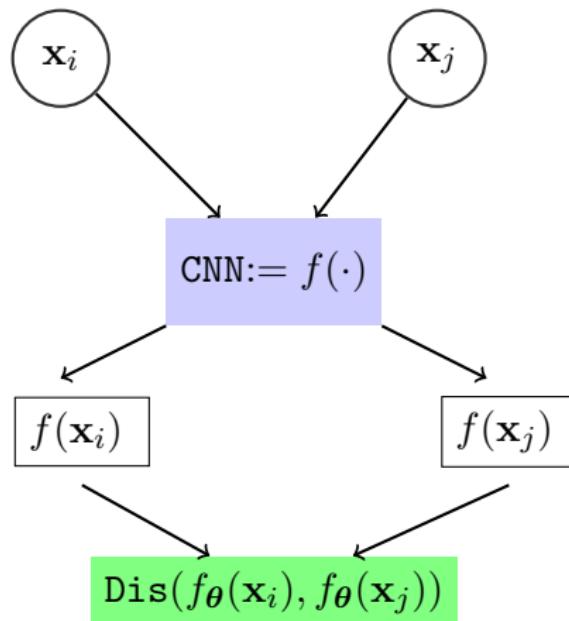

Figure: Scheme of Siamese Network

How to define the distance?

- A model is used to predict the position in feature space.
- A common way is to use a norm of the difference between the encoding of these two images, i.e.,
$$\text{Dis}(\mathbf{x}_i, \mathbf{x}_j) = \|f_{\theta}(\mathbf{x}_i) - f_{\theta}(\mathbf{x}_j)\|_2^2$$
- The important question is how to train the model?
 - ① Loss functions
 - ② how to define the training protocol.

How do we train a Siamese neural network?

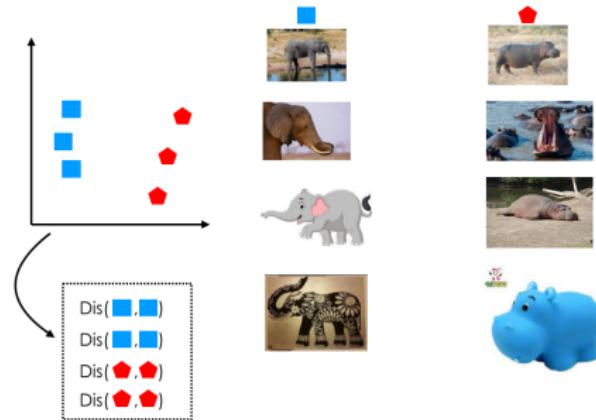

Figure: Note that the CNN, has parameters θ . A *naive* approach is to minimize the loss function $\|f_\theta(x_1) - f_\theta(x_2)\|_2^2$ for all the **positive pairs**

How do we train a Siamese neural network?

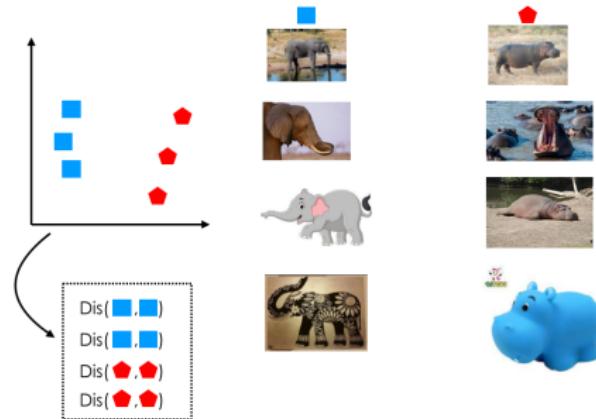

Figure: Note that the CNN, has parameters θ . A *naive* approach is to minimize the loss function $\|f_\theta(x_1) - f_\theta(x_2)\|_2^2$ for all the **positive pairs**

- The model could learn to *embed every input to the same point*, i.e. predict a constant as output. ($\theta = 0$)
- “Neural collapsing”. A possible solution is to use a regularization of the projection space to avoid the prediction as a constant.

Triplet Loss

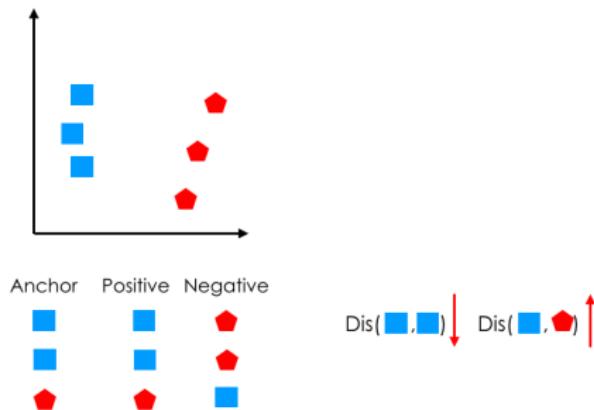

Figure: Triplet Loss: $L(a_i, p_i, n_i) = \max(\text{Dis}_{ap} - \text{Dis}_{an} + \alpha, 0)$.

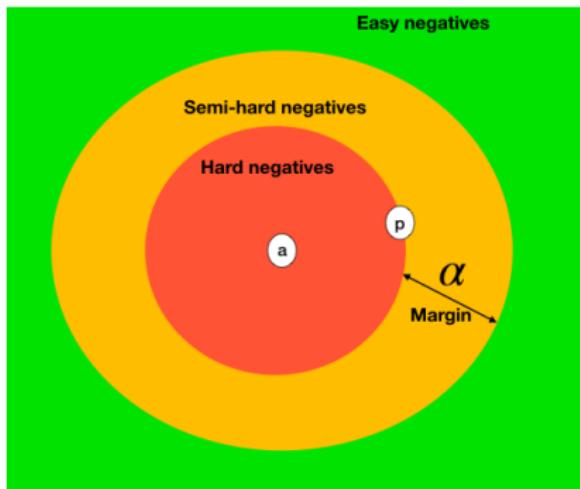

- As Dis_{ap} tend to zero, α play a role of margin, to force $\text{Dis}_{an} \geq \alpha$. α is usually called the *margin*

Contrastive Loss

- For any positive pair of data-points $y_{ij} = 1$ this distance should be small, and for negative pair $y_{ij} = 0$ it should be large.
- Contrastive loss:
$$L(\mathbf{x}_i, \mathbf{x}_j) = y_{ij} \text{Dis}_{ij}^2 + (1 - y_{ij}) \max(\alpha - \text{Dis}_{ij}, 0)^2$$
- Schroff, Florian, et al. Facenet: A unified embedding for face recognition and clustering, CVPR 2015.

Hard negative sampling

- After a few epochs, If (a, p, n) are chosen randomly, it will be easy to satisfy the inequality.

- Random sampling is inefficient to find these hard cases.

Hard negative sampling

Based on their distances, there are three categories of triplets:

- ① Easy triplets, have a loss of 0 (and gradient equal to 0), because $\text{Dis}(a, p) + \alpha < \text{Dis}(a, n)$.
- ② Hard triplets, where the negative is closer to the anchor than the positive, $\text{Dis}(a, n) < \text{Dis}(a, p)$,
- ③ Semi-hard triplets, where negative pair is not closer to the anchor than the positive, but which still have positive loss:
 $(\text{Dis}(a, p) < \text{Dis}(a, n) < \text{Dis}(a, p) + \alpha)$

Smart Mining for Deep Metric Learning, B. Harwood et al, ICCV
2017

Triplet Rank Loss

Figure: Rank between classes

- In general, one can define metric to consider relationship between classes.

Metric Learning in a nutshell

- ① Pick a **parametric distance** $\text{Dis}(\cdot, \cdot)$
- ② Collect **similarity judgements** on data pairs/triples/...
 - $\mathcal{S} = \{(\mathbf{x}_i, \mathbf{x}_j) : \mathbf{x}_i \text{ and } \mathbf{x}_j \text{ are similar}\}$
 - $\mathcal{D} = \{(\mathbf{x}_i, \mathbf{x}_j) : \mathbf{x}_i \text{ and } \mathbf{x}_j \text{ are dissimilar}\}$
 - $\mathcal{R} = \{(\mathbf{x}_i, \mathbf{x}_j, \mathbf{x}_k) : \mathbf{x}_i \text{ is more similar to } \mathbf{x}_j \text{ than to } \mathbf{x}_k\}$
 - Training your model f_{θ} , to minimise a loss function:

$$\arg \min_{\theta} L(\mathcal{S}, \mathcal{D}, \mathcal{R}) + \lambda \text{reg}(\theta) \quad (5)$$

Deep Metric Learning: Second Approach

For a database of c types of objects (individuals)

- ① Solve the metric learning problem as a classification problem of c classes with a final softmax layer. In testing the score of similarity is a compute in the feature space before the use of softmax.
- ② Advantage: Easy use of pretrained networks. You shouldn't bother with sampling triplets.
- ③ Disadvantage: Modification of softmax are required. Score is not directly optimized.

Deep Metric Learning: Second Approach

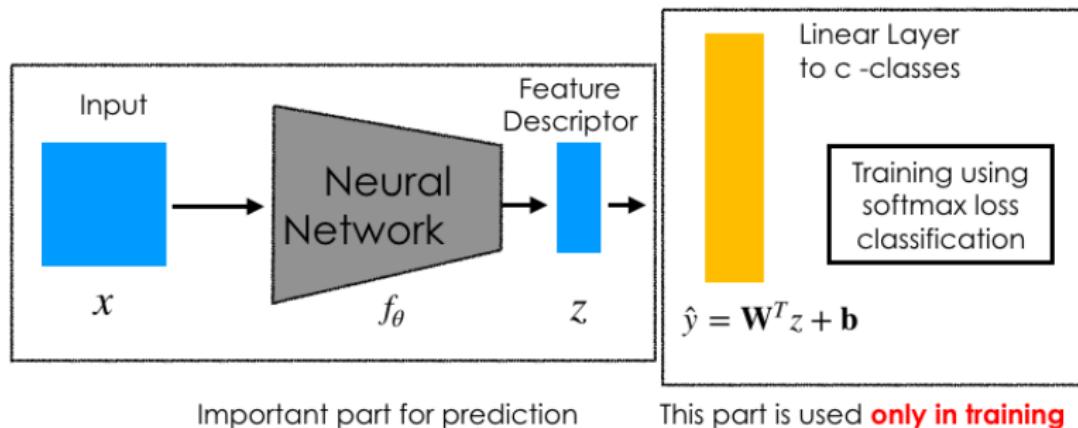

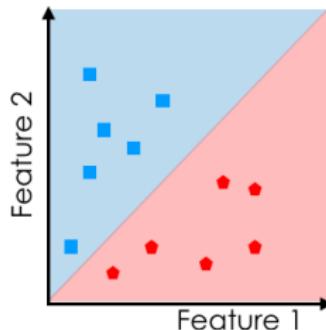

Figure: Metric Learning by means of Supervised Learning

Softmax

Let $z = f_{\theta}(x)$ be the feature vector of the sample x after passing through the model f_{θ} . In the classification setting of c classes, we usually have a linear classification layer $\hat{y} = \mathbf{W}^T z + \mathbf{b}$, where $\mathbf{W} \in R^{n \times m}$ and $\mathbf{b} \in R^m$.

The Softmax Loss for a batch of N samples is defined as:

$$L_{softmax} = -\frac{1}{N} \sum_{i=1}^N \log \frac{\exp(\mathbf{W}_{y_i}^T z_i + \mathbf{b}_{y_i})}{\sum_{j=1}^c \exp(\mathbf{W}_j^T z_i + \mathbf{b}_j)} \quad (6)$$

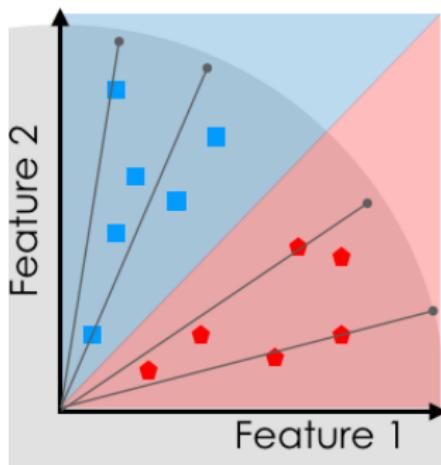

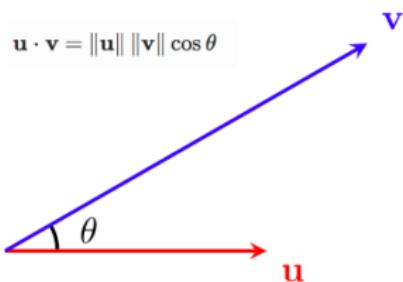

Modified Softmax

- ① Set bias in the last layer to zero, $\mathbf{b} = 0$
- ② Normalize the weight so that $\|\mathbf{W}_j\| = 1$

then,

$$\exp(\mathbf{W}_j^T z_i + \mathbf{b}_j) = \exp(\|\mathbf{W}_j\| \|z_i\| \cos(\theta_{j,i})) = \exp(\|z_i\| \cos(\theta_{j,i}))$$

Modified Softmax

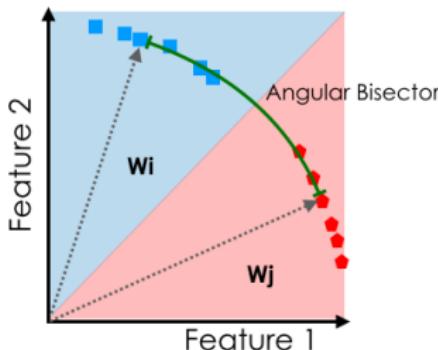

Figure: Modified SoftMax

Decision boundary is harder to make our features discriminative enough.

$$L_{ModSmax} = -\frac{1}{N} \sum_{i=1}^N \log \frac{\exp(\|z_i\| \cos(\theta_{y_i,i}))}{\sum_{j=1}^c \exp(\|z_i\| \cos(\theta_{j,i}))} \quad (7)$$

Geometrically, it means that we assign the sample to class k if the angle between \mathbf{W}_k and z is the smallest among all class center \mathbf{W}_j .

CosFace

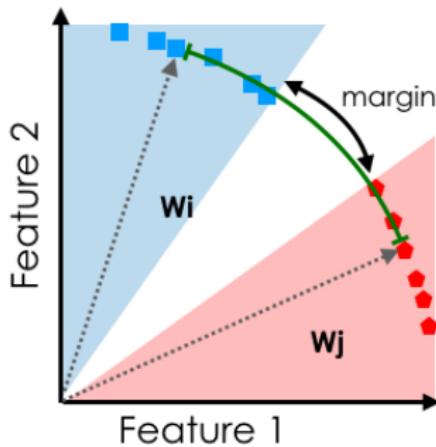

Figure: CosFace (Wang et al. 2018)

Add a normalization for the features z , so $\|z\| = 1$. Add an *scaling* parameter s , and a *margin* parameter m .

$$L_{CosFace} = -\frac{1}{N} \sum_{i=1}^N \log \frac{\exp(s(\cos(\theta_{y_i,i}) - m))}{\exp(s \cos(\theta_{y_i,i}) - m) + \sum_{j \neq y_i} \exp(s \cos(\theta_{i,j}))} \quad (8)$$

Example

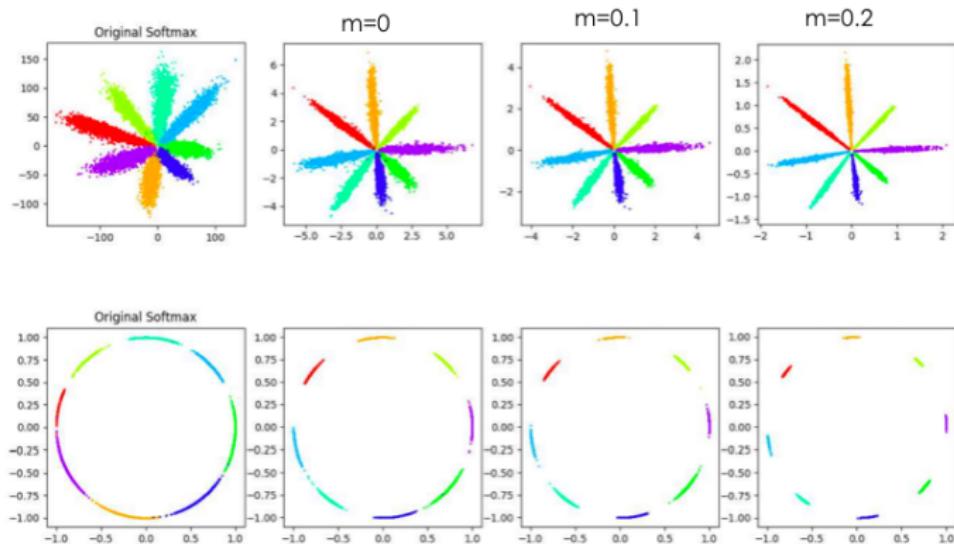

Figure: A toy experiment of different loss functions on eight identities with 2D features. The first row maps the 2D features onto the Euclidean space, while the second row projects the 2D features onto the angular space. The gap becomes evident as the margin term m increases. (Wang et al. 2018)

Adversarial Examples [Goodfellow et al., 2015]

- Given a ML model $f_\theta(\cdot)$ and a *small perturbation* δ , we call \mathbf{x}^{adv} an adversarial example if there exists x , an example drawn from the benign data distribution, such that $f_\theta(\mathbf{x}) \neq f_\theta(\mathbf{x}^{adv})$ and $\|\mathbf{x} - \mathbf{x}^{adv}\| \leq \delta$.
- An human user would still visually consider the adversarial input \mathbf{x}^{adv} similar to or the same as the benign input x
- Usually, we are interested in adversarial examples for benign samples \mathbf{x} , i.e., samples where the model gives a correct prediction.

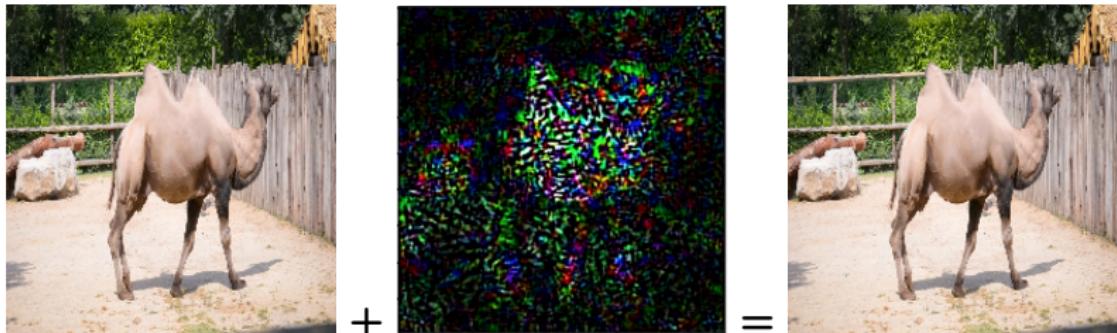

Figure: $\mathbf{x} + \epsilon = \mathbf{x}^{adv}$

Adversarial Gradient

Figure: $-\nabla_{\mathbf{x}}L(f_{\theta}(\mathbf{x}), (0, 0, 1))$

Gradient based Methods

Fast Gradient Sign Method [Goodfellow et al., 2015] Their perturbation can be expressed as

$$\eta = \epsilon \cdot \text{sign}(\nabla_{\mathbf{x}} L(f_{\theta}(\mathbf{x}), y_{\text{true}})) \quad (9)$$

where ϵ is the magnitude of the perturbation.

- The generated adversarial example \mathbf{x}^{adv} is calculated as $\mathbf{x}^{adv} = \mathbf{x} + \eta$.
- This perturbation can be computed by using back-propagation.
- This is a single-step, **untargeted attack**, which approximately minimises the L_{∞} norm of the perturbation bounded by the parameter ϵ .

Gradient based Methods

Fast Gradient Sign Method [Goodfellow et al., 2015] Their perturbation can be expressed as

$$\eta = \epsilon \cdot \text{sign}(\nabla_{\mathbf{x}} L(f_{\theta}(\mathbf{x}), y_{\text{true}})) \quad (9)$$

where ϵ is the magnitude of the perturbation.

- The generated adversarial example \mathbf{x}^{adv} is calculated as $\mathbf{x}^{adv} = \mathbf{x} + \eta$.
- This perturbation can be computed by using back-propagation.
- This is a single-step, **untargeted attack**, which approximately minimises the L_{∞} norm of the perturbation bounded by the parameter ϵ .

Adversarial examples as data augmentation

To avoid overfitting and obtain more robust model: Adversarial Training = Data Augmentation with adversarial examples

Fast Gradient Sign Method II

This single-step attack encourages the network to classify the adversarial example as y_t by assigning

$$\mathbf{x}^{adv} = \mathbf{x} - \epsilon \cdot sign(\nabla_{\mathbf{x}} L(f_{\theta}(\mathbf{x},), y_t)) \quad (10)$$

In reference, the convention is choosing the target class as the least likely class predicted by the network.

Iterative FGSM

This attack extends FGSM by applying it in an iterative manner, which increases the chance of fooling the original network. Using the subscript to denote the iteration number, this can be written as

$$\begin{aligned}\mathbf{x}_0^{adv} &= \mathbf{x} \\ \mathbf{x}_{t+1}^{adv} &= \text{clip}(\mathbf{x}_t^{adv} + \alpha \cdot \text{sign}(\nabla_{\mathbf{x}_t^{adv}} L(f_{\theta}(\mathbf{x}), y_t)))\end{aligned}$$

The `clip(a)` makes each value on a_i of \mathbf{a} is in range $[a_i - \epsilon, a_i + \epsilon]$. This ensures that the max-norm constraint of each component of the perturbation, being no greater than ϵ is maintained. It thus corresponds to projected gradient descent ??, with step-size ∇ , into an L_{∞} ball of radius ϵ around the input \mathbf{x} .

Universal adversarial perturbation

[Moosavi-Dezfooli et al., 2017]

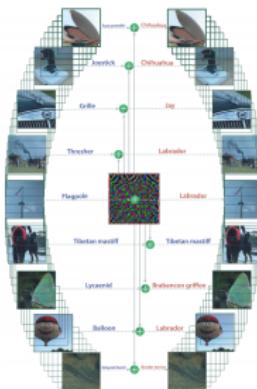

Figure: When added to a natural image, an universal perturbation image causes the image to be misclassified by the deep neural network with high probability

White box Attacks

Without having access to model's parameters, but only prediction value, some works show that is possible to create adversarial examples by free-derivate methods.

Interest of adversarial attacks

- <https://foolbox.readthedocs.io/en/latest/index.html>
- Improve our understanding of deep learning
- Build defences against these attacks
- Improve the robustness of the models
- Reduce the overfitting during training.

Example: Colab

① Simple GANS

<https://colab.research.google.com/drive/1Zft81l92IJreLiLHBwe5n-HZPGSRQFif?usp=sharing>

② Adversarial attacks

<https://colab.research.google.com/drive/1bE5Tyo-p7DF9Q-VDHiEjRNrlq9ABdrCj?usp=sharing>

③ Metric Learning

<https://colab.research.google.com/drive/1lIn2-Akli092jf1npMBwVK8GE1AQEo24?usp=sharing>

Questions?

- ① What is an adversarial example?
- ② Can adversarial examples help to avoid overfitting during training?
- ③ Could you explain a technique to create adversarial examples?
